Server-side Validation:

Invalid input. Negative values are not allowed.

Analysis Question:

1. Explain how CREATE works from form to database

When the user fills out the form and clicks submit, the data is sent to create.php using POST. The system checks the values, calculates the total, and then saves the information into the database.

2. Explain how READ retrieves records

The READ process gets all the saved records from the database using a SELECT query. It then displays the data in a table so the user can see the transactions.

3. Explain why UPDATE needs an ID

UPDATE needs an ID because each record must be identified individually. Without the ID, the system would not know which transaction to change.

4. Explain why prepared statements are important

Prepared statements protect the system from SQL injection attacks. They make sure user input does not directly interfere with the SQL query.

5. Explain how functions improved your code

Functions made the code cleaner and easier to understand. They allowed me to reuse logic like validation and redirection instead of writing the same code multiple times.
